Part I

Preface

1 Introduction

The package **miscset** provides several R tools to read, create, modify and write different types of data. In the following examples, all available functions will be presented including explanations of their usage. Find the source code online at github.

2 Installation

To install the package call the command install.packages("miscset") within the R console or run R CMD install miscset from a terminal. To use it the library or require function load the package.

```
require(miscset)
## Loading required package: miscset
```

Part II

Functions

3 Apply Functions

3.1 Apply a function on a data frame by a grid = gapply

To apply a function on a subset of a dataset, all named columns are used to create a grid for which each unique combination is used to extract the rows in the data.frame. Multicore support is implemented by mclapply. The grid can be extracted by the function levels and a row binding of elements that can be coerced to data.frames is implemented in the method as.data.frame.

```
f <- function (x) c(conc.diff = diff(range(x$conc)), uptake.sum=sum(x$uptake))</pre>
d <- gapply(CO2, c('Type', 'Treatment'), f)</pre>
levels(d)
            Type Treatment
##
## 1
          Quebec nonchilled
## 2 Mississippi nonchilled
## 3
          Quebec
                     chilled
## 4 Mississippi
                     chilled
head(as.data.frame(d))
##
     conc.diff uptake.sum
                                   Type Treatment
## 1
           905
                     742.0
                                Quebec nonchilled
           905
## 2
                     545.0 Mississippi nonchilled
## 3
           905
                     666.8
                                Quebec
                                           chilled
## 4
           905
                     332.1 Mississippi
                                           chilled
```

4 Numeric Functions

4.1 Generate triangular numbers - ntri

The function generates a series of triangular numbers of length n according to oeis.org.

```
ntri(12)
## [1] 0 1 3 6 10 15 21 28 36 45 55 66
```

4.2 Scale numeric vectors - scale0

The function scales all values in a numeric vector from 0 to 1.

```
scale0(0:10)
## [1] 0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
scale0(-1:3)
## [1] 0.00 0.25 0.50 0.75 1.00
scale0(2:3)
## [1] 0 1
```

5 Data Formatting

5.1 Transform to squared matrix - squarematrix

The function squarematrix can generate a symmetric (square) matrix from an unsymmetric matrix by using the column and row names and filling empty pairs with NA.

5.2 Generate a pairwise list - enpaire

The function enpaire creates a pairwise list of matrix values. The result is a data.frame that contains a column for the names of each dimension and the upper and lower triangle values. Unsymmetric matrices are transformed by squarematrix (see previous section).

```
M <- matrix(letters[1:9], 3, 3, dimnames = list(1:3,1:3))
M</pre>
```

```
## 1 2 3
## 1 "a" "d" "g"
## 2 "b" "e" "h"
## 3 "c" "f" "i"

enpaire(M)

## row col lower upper
## 1 1 2 b d
## 2 1 3 c g
## 3 2 3 f h
```

6 Data Exporting

6.1 Create a latex document containing a table - textable

This function enhances the functionality of the xtable function from the similar named package. The output of xtable is captured, processed and then written to a file. The file contains also latex header for an A4 portrait or landscape article. The function is called with the following syntax: textable(d, file, caption, rownames, landscape, pt.size, margin, digits, align, label)

file is a character string with the name to the file of the function output. caption is a character string with the table's title. rownames is logical and allows to switch printing of row names on and off. landscape is logical for the orientation of the page, pt.size uses an integer value to define the size of the characters. margin sets a margin between page and table borders in cm. digits defines the number of digits to print for numeric values. With align the column alignements can be set. Either a single value or a value for the row names column plus each column in d. The possible values are 'r', 'c', 'l' for alignemt to the right, center or left.

```
textable(head(trees,3), rownames=T, digits=4, align='c', caption='R dataset "trees".')
## \documentclass[a4paper,10pt]{article}
## \usepackage[a4paper,margin=2cm]{geometry}
## \begin{document}
## % latex table generated in R 3.1.0 by xtable 1.7-3 package
## % Thu Jun 12 10:20:27 2014
## \begin{table}[ht]
## \centering
## \begin{tabular}{cccc}
##
    \hline
## & Girth & Height & Volume \\
    \hline
## 1 & 8.3000 & 70.0000 & 10.3000 \\
   2 & 8.6000 & 65.0000 & 10.3000 \\
    3 & 8.8000 & 63.0000 & 10.2000 \\
##
     \hline
## \end{tabular}
## \caption{R dataset "trees".}
## \end{table}
## \end{document}
```

7 Text String Manipulation

7.1 Prepend zeroes to unify number lengths - leading0

The function leading 0 aims to create e.g. index names with a common string length. It creates character strings from numeric values while attaching 0 in front of the number up to a certain length of total digits of each string.

```
paste0("page", leading0(8:10, 3))
## [1] "page008" "page009" "page010"
```

7.2 Extract substrings by pattern - strextr

The function strextr splits strings in a character vector by sep and extracts all substrings matching a given pattern.

```
s <- c("a1 b1 c1", "a2 b2", "aa a1", "aa", "b1 a1", "bb ab a1")
strextr(s, "^[ab][[:digit:]]$")
## [1] NA
          NA
                 "a1" NA
strextr(s, "^[ab][[:digit:]]$", mult = T)
## [[1]]
## [1] "a1" "b1"
##
## [[2]]
## [1] "a2" "b2"
##
## [[3]]
## [1] "a1"
##
## [[4]]
## [1] NA
##
## [[5]]
## [1] "b1" "a1"
##
## [[6]]
## [1] "a1"
strextr(s, "^[ab][[:digit:]]$", mult = T, unlist = T)
## [1] "a1" "b1" "a2" "b2" "a1" NA
                                     "b1" "a1" "a1"
strextr(s, "^[c][[:digit:]]$")
## [1] "c1" NA NA NA
                                NA
```

7.3 Extract substrings by splitting - strpart

Similar to strextr the function strpart supplies a method to extract a substring, but by defining the nth part of the string split by the separator given in sep.

```
strpart(s, " ", 2)
## [1] "b1" "b2" "a1" NA "a1" "ab"
```

7.4 Reverse strings - strrev

With strrev you can create the reversed version of strings.

7.5 Multiple pattern replacement - msub, mgsub

msub and mgsub behave like sub and gsub but they replace multiple patterns. Replacement is done in order of the pattern input, and multicore support is enabled by mclapply from the parallel package.

```
## [1] "a1 b1 c1" "a2 b2"
                               "aa a1"
                                          "aa"
                                                      "b1 a1"
                                                                 "bb ab a1"
msub("A", "X", s)
## [1] "a1 b1 c1" "a2 b2"
                               "aa a1"
                                          "aa"
                                                      "b1 a1"
                                                                 "bb ab a1"
mgsub("A", "X", s)
## [1] "a1 b1 c1" "a2 b2"
                                          "aa"
                                                      "b1 a1"
                               "aa a1"
                                                                 "bb ab a1"
```

8 Pattern Matching

8.1 Get index of expression - gregexprind

```
## [1] "a1 b1 c1" "a2 b2" "aa a1" "aa" "b1 a1" "bb ab a1"
gregexprind("a", s, 1)
## [1] 1 1 1 4 4
gregexprind("a", s, 2)
## [1] NA NA 2 2 NA 7
gregexprind("a", s, "last")
## [1] 1 1 4 2 4 7
```

8.2 Multiple pattern search - mgrepl

With mgrepl(patterns, text, ...) you can search for more than one regular expression, and use a logical function to combine the results for each single expression.

```
## [1] "a1 b1 c1" "a2 b2" "aa a1" "aa" "b1 a1" "bb ab a1"

mgrepl(c("a","b"), s, any)

## [1] TRUE TRUE TRUE TRUE TRUE

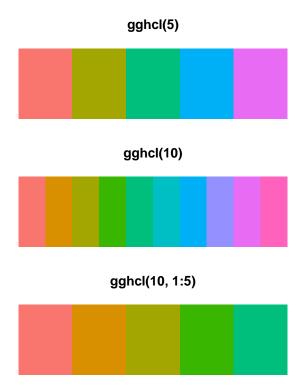

mgrepl(c("a","b"), s, all)

## [1] TRUE TRUE TRUE FALSE FALSE TRUE
```

9 Graphical Tools

9.1 Create a color palette - gghcl

gghcl() creates color palettes. It enhances the hcl function. See some examples:

10 System Tools

10.1 List details from and remove all objects - lsall, rmall

With lsall(envir, ...) all object names, their length, class, mode and size is returned in a data.frame from a specified environment. rmall(...) removes the complete list of objects at the global environment.

```
lsall()
```

```
## Environment: R_GlobalEnv
## Objects:
## Name Length Class Mode Size Unit
## 1 M 9 matrix character 1.3 Kb
## 2 d 4 gapply list 4.9 Kb
## 3 f 1 function function 2.5 Kb
## 4 s 6 character character 392.0 byte

rmall()
lsall()

## Environment: R_GlobalEnv
## Objects:
## NULL
```
